

Project 03

First Coding Update

Due date: 03/27

Points: 100

In this part you should have your data preprocessing, segmentation and feature extraction implemented. *Please create a GitHub repository for the project*, if you already have a GitHub repository for the course, feel free to use that one.

What to do and deliver?

- A report (no page limit, but try to be concise; 1000-2000 words should suffice). Write the report as part of the README.md of your GitHub repository. Include:
 - A list of the methods already applied for data pre-processing and feature extraction (10 points).
 - A justification for why you decided to use these algorithms (30 points). For instance, if you used Canny edge detection and the Hough transform to detect lines, say why you believe this feature extraction is good for your project.
 - A few illustrations demonstrating how your methods processed the training data, for instance show a few segmentation results (20 points).
- Push your current code to your project repository (40 points).
 - This code should implement what you described in the report. Provide instructions on how to run your code on a data sample (*attach this data sample to the code push*).

Note 1 (for teams): Explain individual contributions of each team member (this is needed to have this assignment graded).

Submission: PDF file with the GitHub link.
