

Project 05

Final Update

Due date: 05/01

Points: 100

The aim of this last part of the semester project is to test your solutions on unknown data. By "unknown data" I mean a set of samples not used (or seen) when you were designing your method in previous phases.

Deliverables:

- A report (no page limit, but try to be concise; 1000-2000 words should suffice) as a separate section of the readme.md in your GitHub that includes:
 - Description of the test database you collected or downloaded: What is the size of the database? What is different when compared to the training and validation subsets? Why do you believe these differences are sufficient to test your final programs? (10 points)
 - A classification accuracy achieved on the test set. Use the same metrics as in the previous phase (training, validation). (20 points)
 - Most of you should see worse results on the test set when compared to the results obtained on train/validation sets. You should not be worried about that, but please provide the reasons why your solution performs worse (with a few illustrations, such as pictures or videos). What improvements would you propose to lower the observed error rates? (20 points)
- Imagine you want to present your final program to a friend or investor. And this presentation should be short and illustrative (that is: show what you did and how good it is). Prepare a short video presenting how your final program works. Here are [good examples](#) prepared by former CV students. (20 points)
- Push your final (to be graded) code along with instructions on how to run it. Your program(s) should pick one random sample from the test set and present the processing result. We should be able to run your programs without any edits -- please double check before submission that the code is complete. (30 points)

Note 1 (for teams): explain individual contributions of each team member (this is needed to have this assignment graded).

Note 2 (NNs): If you opted to add NNs to your project, include comparisons to your original methods and explain your observations in the report (you can decide what to include in the video).

Submission: PDF file with the GitHub link.
